# ACTIVITY

1) 1. I would recommend contrast stretching to improve the visibility of darker tissues in X-ray image.

2. Contrast stretching expands the range of gray level intensities, making small intensity differences more noticeable. It improves the contrast between darker tissues & selectively stretches while retaining important bone details.

3. The darker tissues will become more distinguishable, & differences between gray levels will become clearer. The enhanced image will provide better visibility of anatomical structures & may help the doctor examine the X-ray more effectively.

2) 1. I would recommend the logarithmic transformation to improve the visibility of the dark CCTV image.

2. logarithmic transformation expands the lower range of pixel intensities & compresses the higher range. Since most pixel values lie between 0 and 40, it makes details in dark regions more visible. Negative transformation simply reverses the the intensity values & may not enhance details in the dark regions as effectively.

3. The parking lot will appear brighter and objects such as vehicles, people and obstacles will become more visible. Details that were difficult to distinguish in the original dark image will become clearer, although noise may also become more noticeable.

3) 1. I would apply contrast stretching to improve the contrast between fingerprint ridges & valleys.

2. Contrast stretching expands the intensity range of the fingerprint image, making small differences between ridges and valleys more noticeable. This helps preserve and reveal fine details and improves quality of image for fingerprint recognition.

3. Logarithmic transformation would expand lower intensity values and compress higher intensity values, which improves visibility.
